INTRODUCTION			RESULTS																																		
<ul style="list-style-type: none"> Pain associated with diabetic peripheral neuropathy (DPN) is treated medically with antineurals, tricyclic antidepressants, and serotonin-norepinephrine reuptake inhibitors which are often not satisfactory long-term¹. Spinal Cord Stimulation (SCS) is an effective treatment alternative per 3 randomized controlled trials (RCTs)^{2,3,4} which consistently demonstrate that SCS is more effective than conventional medical management (CMM) for the treatment of painful DPN. The difference in treatment success between SCS and control in the RCTs ranged 52 - 58% for the primary endpoint in the intention-to-treat populations²⁻⁵, and subjects reported improvements in EQ-5D quality of life (QoL) index scores of 0.12 - 0.38 at 6-months²⁻⁷. We qualitatively looked for consistency in outcomes between published RCT results for SCS and registry data to assess "real-world" therapy efficacy for painful DPN. 	<ul style="list-style-type: none"> There were 84 subjects enrolled in the registry indicated for DPN, and 69 implanted at the time of data cutoff (Table 1). Subjects experienced a mean (standard deviation, SD) reduction in leg pain at 1st follow-up of 2.6 (3.6) on 0 - 10 pain scale from 6.8 (2.5) at baseline (n=16) [Figure 1]. QoL measured by the EQ-5D index was improved at 1st follow-up by a mean (SD) of 0.17 (0.26) from 0.40 (0.26) at baseline (n = 30), with 60.0% of subjects experiencing a minimally clinically important difference⁸ [Figure 2]. Subjects reported decreased disability with 30% of subjects improving to a better disability category and 45% remaining in the same disability category as determined by the Oswestry Disability Index (ODI) (n=20) [Figure 3]. ODI categories include minimal disability, moderate disability, severe disability, crippled, and bed-bound. Baseline medications were recorded in 58 subjects with decreased usage or no change in usage of baseline medications reported by 62.0% of subjects (36/58), with 37.9% of subjects (22/58) decreasing dosage in at least 1 baseline medication. 		<p>Table 1. Baseline characteristics in DPN subjects. <p>MATERIALS & METHODS</p> <ul style="list-style-type: none"> Registry data was obtained from the Medtronic Product Surveillance Registry. An analysis of outcomes including leg pain, QoL, disability, and medication usage was conducted using paired data at baseline and 1st follow-up (6- or 12-months) collected between November 2012 and October 2023 from subjects with either a primary or secondary DPN indication. Not all subjects in the registry had data at both baseline and 1st follow-up. Only subjects with paired data at baseline and 1st follow-up were included in the analysis. Sample size noted is indicative of data availability. 	<p>Figure 1. Leg pain measured by VAS in DPN subjects from baseline to first follow-up (n=16).</p> <p>Figure 2. EQ-5D index Scores in DPN subjects at baseline and first follow-up (n=30).</p> <p>Figure 3. Change in Oswestry Disability (ODI) disability categories in DPN subjects from baseline to first follow-up. Data presented as n (% of total).</p>		<p>CONCLUSIONS</p> <ul style="list-style-type: none"> An analysis of data from a clinical registry suggests that SCS provides pain relief, and improvements in quality of life and disability for patients with painful DPN. As a newer indication, the volume of registry subjects with DPN is relatively low. More data is needed. Collectively, robust published outcomes from 3 RCTs in combination with preliminary data from a clinical registry support the efficacy of SCS for painful DPN for the lower extremities that should be considered when CMM is unsatisfactory. Registry data on SCS for painful DPN will continue to be collected as more DPN patients gain access to SCS therapy. 	<p>REFERENCES</p> <ol style="list-style-type: none"> Sloan G, et al.
